The boiling point of A is that at which the mole fraction of A is 1. The boiling point of B is that at which the mole fraction of A is 0. In this example, A is the more volatile component and therefore has a lower boiling point than B. The upper curve in the diagram is called the dew-point curve while the lower one is called the bubble-point curve.

Because the freezing point of pure water is 0°C, the sucrose solution freezes at -0.68°C. A similar property of solutions is boiling point elevation. A solution boils at a slightly higher temperature than the pure solvent. The change in the boiling point is calculated from  $\Delta T_b = K_b m$

Latent Heat and Freezing and Boiling Points. A calorie is the amount of heat it takes to raise the temperature of 1 gram (0.001 liters) of pure water 1 degree C at sea level. It takes 100 calories to heat 1 g. water from 0°, the freezing point of water, to 100° C, the boiling point.

Melting Point and Freezing Point. Pure, crystalline solids have a characteristic melting point, the temperature at which the solid melts to become a liquid. The transition between the solid and the liquid is so sharp for small samples of a pure substance that melting points can be measured to 0.1 °C. The melting point of solid oxygen, for example, is -218.4 °C.

On the 5th of February, we learnt about the boiling point of water. Firstly, we conducted an experiment to find out the boiling point of water. The aims of our experiment were: To learn how to heat a liquid in a beaker. To take measurements of the temperature of the liquid and draw a graph to show how temperature changes with time.

The proportionality constant,  $K_f$ , is called the molal freezing-point depression constant. It is a constant that is equal to the change in the freezing point for a 1-molal solution of a nonvolatile molecular solute. For water, the value of  $K_f$  is -1.86°C/m. So the freezing temperature of a 1-molal aqueous solution of any nonvolatile molecular ...

Boiling point elevation is the raising of a solvent's boiling point due to the addition of a solute. Similarly, freezing point depression is the lowering of a solvent's freezing point due to the addition of a solute. In fact, as the boiling point of a solvent increases, its freezing point decreases. An example of this would be the addition of salt to an icy sidewalk.

Freezing point depression (the freezing point goes down) occurs when solute is added to the pure solvent. Thus the amount of depression depends on the amount of solute added into the solution, i.e depends on the molarity (M) of the solution.
